Some Applications of Milliken's Tree Theorem

The structures, countable discrete set, the rationals, and the Rado graph, have finite big Ramsey degree. For all of these structures, Milliken's Tree Theorem can be used to prove this.

Computability 00000000 Miliken's Tree Theorem

Rationals 0000

Rado 0000

Coloring Structures

- Let \mathcal{B} be an infinite structure and \mathcal{A} is any finite substructure of \mathcal{B} .
- $\binom{\mathcal{B}}{\mathcal{A}}$ are copies of \mathcal{A} in \mathcal{B} .
- For $\ell \leq k$, the notation

$$\mathcal{B}
ightarrow (\mathcal{B})_{k,\ell}^{\mathcal{A}}$$

means that for every coloring $f : \binom{\mathcal{B}}{\mathcal{A}} \to k$ there exists an isomorphic substructure \mathcal{B}' of \mathcal{B} such that $|f^{-1}\binom{\mathcal{B}'}{\mathcal{A}}| \leq \ell$.

Rado 0000

Finite Big Ramsey Degree

- For a finite substructure A of B, the *big Ramsey degree of A in B* is the least number *l* ∈ ω, if it exists, such that B → (B)^A_{k,l} for all k ∈ ω, in which case we say that the big Ramsey degree of A is *finite*.
- We say that a structure *B* has finite big Ramsey degrees if, for every finite substructure *A* of *B* has finite big Ramsey degree.
- All 3 of our examples have finite big Ramsey degree.

Theorem

There is a copy of \mathcal{B} *such that, for all* \mathcal{A} *, there is a* $\ell_{\mathcal{A}}$ *and computable coloring,* $C_{\ell_{\mathcal{A}}}$ *, of* \mathcal{B} *with* $\ell_{\mathcal{A}}$ *colors such that*

- (Existence) $\mathcal{B} \to (\mathcal{B})^{\mathcal{A}}_{k,\ell_{\mathcal{A}}}$.
- (Tightness) In all the copies B' of B, for all j ≤ ℓ_A, there is a copy of A with color j from C_{ℓ_A} appearing.

Milliken's Tree Theorem is used to show $\ell_{\mathcal{A}}$ exists. Tightness is related to the (model theoretic) types of \mathcal{A} coded into a yet to be determined superstructure of \mathcal{B} allowing for a larger language. A color for each type. We will later discuss how these copies of \mathcal{A} and the types or colors of \mathcal{A} occur within \mathcal{B}' .

For ω , $\ell_n = 1$ for all *n*. The superstructure is just ω .

Rado 0000

When \mathcal{A} is a singleton

Here we are just coloring the domain. \mathcal{B}' can be created as the limit of finite substructures \mathcal{B}'_s of \mathcal{B} . Run the greedy algorithm to find a \mathcal{B}'_{s+1} for all colors. It that fails we get a copy of \mathcal{B} with fewer colors. Repeat till it works or we are down to a single color. So nonuniformly computable. Hence provable in *RCA*₀.

Rado 0000

Largely Extendable

- All our structures are computable. Hence there is a one-to-one computable enumeration of the domains. Say *d_i* for *i* ∈ N. Sometimes we need these enumerations to have some special properties related to the structure.
- We say d_i in the domain of A is *large* if *i* is large.
- When A has size 3, we can use this notion of large to define when a copy A in B' is *largely extendable* and *large companions*.

Theorem (Largeness)

For all our \mathcal{B} , for all our \mathcal{A} , each appearance of \mathcal{A} in \mathcal{B}' is largely extendable. Moreover, we can find large companions with the same color as our copy of \mathcal{A} w.r.t. $C_{\ell_{\mathcal{A}}}$.

Miliken's Tree Theorem 0000 Rationals 0000 Rado 0000

Pairs inside an Extension of Q

We will consider the structure $\mathbb{Q}^* = (2^{<\omega}, <_{\mathbb{Q}}, \wedge)$. Let U be a subset of $2^{<\omega}$ such that $(U, <_{\mathbb{Q}})$ is a copy of \mathbb{Q} . Let U^{\wedge} be the meet closure of U. Let $\mathcal{U}^* = (U^{\wedge}, <_{\mathbb{Q}}, \wedge)$. Fixed an enumeration e of $2^{<\omega}$ such that if |e(i)| < |e(j)| then i < j.

Theorem (Selective Largeness)

For all z, we can computably find an copy of $\{\sigma \land \tau, \sigma, \tau\}$, where $|\sigma| < |\tau|$ iff $q_{\sigma} < q_{\tau}$ (so the pair $\{\sigma, \tau\}$ is colored 1), and $|\sigma \land \tau| > z$, in \mathcal{U}^* which is largely extendable. Moreover, there are large companions with the same color. Similarly for $\{\sigma \land \tau, \sigma, \tau\}$, where is not the case that $|\sigma| < |\tau|$ iff $q_{\sigma} < q_{\tau}$ (so the pair σ, τ is colored 0),

The proof makes several critical uses of the fact that $(U, <_{\mathbb{Q}})$ is a copy of \mathbb{Q} .

Let $C_I(\sigma, \tau) = C_I(\sigma \land \tau, \sigma, \tau)$. We can show the product coloring codes *K*.

Rado 0000

 $\mathcal{R} \to (\mathcal{R})_{k2}^{\mathcal{K}_2}$

Take a coloring of all copies of \mathcal{K}_2 in \mathcal{R} . Fix *C* not computable. Then there is a subcopy \mathcal{R}' of \mathcal{R} where the copies of \mathcal{K}_2 need just 2 colors and \mathcal{R}' does not compute *C*. This is cone avoidance and done via forcing. So weaker than ACA_0 .

We need to explore why \mathcal{K}_2 in \mathcal{R} is different from 2 in \mathbb{Q} .

It is partially open how the statement $\mathcal{R} \to (\mathcal{R})_{k,2}^{\mathcal{K}_2}$ is related to other statements weaker than *ACA*. A number of results appear in our paper.

Computability 000000000 Miliken's Tree Theorem

Rationals 0000 Rado 0000

Strong subtrees

Definition

A *tree* is a subset *T* of $\omega^{<\omega}$ as follows:

- there exists a *root* $\rho \in T$ such that $\rho \preceq \sigma$ for all $\sigma \in T$;
- if $\sigma, \tau \in T$ then also $\sigma \land \tau \in T$;
- every $\sigma \in T$ there are finitely many $\tau \in T$ such that $\sigma \prec \tau$ and there is no τ' such that $\sigma \prec \tau' \prec \tau$.

Definition

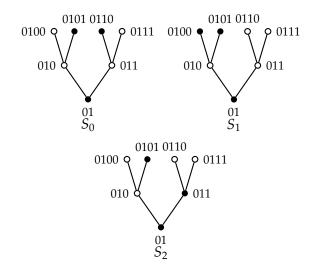

For each $n \in \mathbb{N}$, let $T(n) = \{\sigma \in T : |\tau \in T : \tau \prec \sigma| = n\}$ and height $(T) = \sup\{n + 1 \in \mathbb{N} : T(n) \neq \emptyset\}$.

Definition

Let $U \subseteq T$ be trees. *U* is a *strong subtree* of *T* if there is a *level function f* : height(*U*) \rightarrow *T* such that for all *n* < height(*U*), if $\sigma \in U(n)$ then $\sigma \in T(f(n))$. A node $\sigma \in U$ is *k*-branching in *U* if and only if it is *k*-branching in *T*.

Miliken's tree theorem

Definition

Given a tree *T*, let $S_{\alpha}(T)$ denote the class of all subtrees of *T* of height $\alpha \leq \omega$.

Theorem (Milliken's tree theorem 1979)

Let *T* be an infinite tree with no leaves. For all $n, k \ge 1$ and all $c : S_n(T) \to k$ there is a $U \in S_\omega(T)$ such that *c* is contant on $S_n(U)$. If we color *T* by levels we get Ramsey's Theorem. We will use $T = 2^{<\omega}$.

Rado 0000

Coding Q to have just 2 embeddings

We want to code Q by a set of the nodes *U* such that *U* is antichain; every node in U^{\wedge} , the meet closure of *U*, has a unique length; $U^{\wedge} - U$ is effective isomorphic via *g* to $2^{<\omega}$; and, for all $\sigma \in U$, for all τ , if $|\tau| > |\sigma|$, $\sigma(|\tau|) = 0$ (the passing number of τ by σ is 0). Each leaf in *U* codes a rational as above. Within U, $<_{\mathbb{Q}}$ is just $<_L$. Nodes in $U^{\wedge} - U$ will be called *meets*. Now pairs of leaves have exactly one of two types, one of each color, 0 or 1.

By the above we know these types appear in every subcopy of U which is a dense linear order under $<_L$ without end points. So we have tightness.

Rado 0000

Using Miliken's Tree Theorem

Using all this we can create an effective isomorphism h from $2^{<\omega}$ to U such that: the image of a strong subcopy of $2^{<\omega}$ is a subcopy of \mathbb{Q} ; the preimage of every pair of leaves is embedded in a unique copy of $S_3(2^{<\omega})$; and the image of every copy of $S_3(2^{<\omega})$ contains exactly one pair of leaves of each type. The preimage of colorings of a type result in a coloring of $S_3(2^{<\omega})$. Now use Miliken's Tree Theorem. Take the image of the result. Repeat for the other type.

Rado 0000

Joyce Trees and ℓ_n for the Rationals

The closure of *n* leaves under meets inside U^{\wedge} forms a *Joyce* tree of size *n*. The number of nonisomorphic trees is *n*th odd tangent number. All have 2n - 1 nodes.

We can show these types appear in every subcopy of *U* which is a dense linear order under $<_L$ without end points. (Tightness)

This gives us ℓ_n for the rationals.

▲ロト ▲ □ ト ▲ □ ト ▲ □ ト ● ● の Q ()

An Order Definable from the Rado Graph

Let $\mathcal{R} = (V, E)$ be a computable Rado graph. For i < j, let $\sigma_j(i) = 1$ iff there is an edge from j to i and 0 otherwise. Thus $|\sigma_j| = j$. Define $i <_{\mathcal{R}} j$ iff $\sigma_i <_L \sigma_j$. Call $(V, E, <_{\mathcal{R}})$ the *Joyce Rado Graph*. $(V, <_{\mathcal{R}})$ is a copy of \mathbb{Q} .

Theorem (ACA)

Let (V', E) be a subcopy of the Rado Graph inside \mathcal{R} then there is subcopy (V'', E) of the Rado graph inside (V', E) where $(V'', E, <_{\mathcal{R}})$ is isomorphic to $(V, E, <_{\mathcal{R}})$.

For finite substructures A of the ordered Rado Graph, the ℓ_A for the Rado graph and for the ordered Rado graph are the same.

Computability

Rationals 0000 Rado 0000

$\ell_{\mathcal{A}}$ for the Joyce Rado Graph

The collection of all σ_i is effectively isomorphic to $2^{<\omega}$ under $<_L$. Whether there is an edge between j and i is determined by the passing number of σ_i by σ_j . We can code this, like Q, by antichain U. But we have to remove the restriction there on the passing number. Let $c(\sigma)$ be this coding.

For the completely (dis)connected graph of size *n*, everything works like for subset of set *n* in the rationals. The passing number is constant.

If the meet of $c(\sigma)$ and $c(\tau)$ is longer than $c(\rho)$ then the passing number of $c(\sigma)$ and $c(\tau)$ by $c(\rho)$ agreed. Hence a finite graph \mathcal{G} limits the number of Joyce trees which can code \mathcal{G} . But they can be counted and appear in every subcopy of a Joyce Rado Graph.

Rado 00●0

 $\mathcal{R} \to (\mathcal{R})_{k2}^{\mathcal{K}_2}$, Again

How we code \mathcal{K}_2 for \mathcal{R} is exactly how we code a pair for \mathbb{Q} . But the first satisfies cone avoidance and the second codes *K*.

Any subcopy of the rationals is a copy of Q w.r.t. to original ordering. We needed this fact for selective largeness and hence to code *K*. With a Rado graph we can defined an ordering $<_{\mathcal{R}}$ which gives us copy of Q. Any subcopy of a Rado graph contains a copy of Q w.r.t. $<_{\mathcal{R}}$, possibly properly. That provides enough room for cone avoidance for \mathcal{A} of size 2. Using *ACA* we can find a subordering which is a copy of Q w.r.t. $<_{\mathcal{R}}$.
