Applications of representation theory to statistical problems

Lecture by Persi Diaconis Notes by Dustan Levenstein

Examples of how statisticians could use representation theory.

- (1) Spectral analysis of Time series (babies in New York City)
- (2) Ranked data (election data)
- (3) Representations of the unitary group U_n (relating to zeroes of the Riemann zeta function)
- (4) Monster group

1 Time Series

Suppose we have numbers $f_0, \ldots, f_{N-1} \in \mathbb{R}$ which we think of as a signal. We look for patterns using the discrete Fourier transform

$$\hat{f}(j) = \sum_{k=0}^{N-1} f(k) e^{2\pi i j k/N}.$$

We can recover the signal by the Fourier inversion theorem,

$$f(k) = \frac{1}{N} \sum_{j=0}^{N-1} \hat{f}(j) e^{2\pi i j k/N}.$$

Suppose one $\hat{f}(j)$ is bigger than the rest: then to a good approximation, f(k) is a simple periodic signal.

For example there was a blackout in New York City. The New York Times said there was a big spike in births 9 months after the blackout. There were about 400 kids born every day, and there was a 7 day periodicity to birth rates (fewer kids born on weekends), as well as a 3 year periodicity. Once these factors were removed there was no evidence of a spike.

2 Ranked Data

Suppose we have a study where you taste four chocolates, and rank them from 1 to 4.

Elections: You rank the candidates.

Card shuffling machine: Generates lots of permutations.

In all of these examples, the data is $\sigma_1, \ldots, \sigma_N \in S_n$. We have the associated function

$$f(\sigma) = \#n\{\sigma_n = \sigma\}.$$

Applying the Fourier transform associated to the group S_n gives

$$\hat{f}(\lambda) = \sum_{\sigma} f(\sigma) \rho_{\lambda}(\sigma),$$

where

$$\rho: S_n \to GL_{d_\lambda}(V)$$

is the corresponding irreducible representation and λ runs over all partitions of n. We can recover

$$f(\sigma) = \frac{1}{|G|} \sum_{t} d_{\lambda} T_n(\hat{f}(\rho_{\lambda})\overline{\rho}_{\lambda}(\sigma)).$$

Example In the American Psychological Association election data, we have 5 candidates being ranked from 1 to 5, and we can see how many people voted for each permutation of 5.

| Ranking | No. of votes cast of this type | Ranking | No. of votes cast of this type | Ranking | No. of votes cast of this type | Ranking | cast of this type |

| 45321 | 31 | 34521 | 107 | 23041 | 52 | 12534 | 35 |
| 45312 | 54 | 34512 | 133 | 20014 | 53 | 12453 | 29 |
| 45931 | 34 | 34251 | 62 | 23451 | 52 | 12435 | 27 |
| 40201 | 24 | 34215 | 28 | 23415 | 186 | 12354 | 28 |
| 40210 | 00 | 34152 | 87 | 23154 | 100 | 10245 | 30 |

We can look at what percentage of people ranked person i in position j — it looks pretty flat. Candidate 3 appears to be the favorite, but there is significant vote against candidate 3. This summarizes the original data by 16 numbers. Is it a good summary?

| | | | Rank | | |
|-----------|----|----|------|----|----|
| Candidate | 1 | 2 | 3 | 4 | 5 |
| 1 | 18 | 26 | 23 | 17 | 15 |
| 2 | 14 | 19 | 25 | 24 | 18 |
| 3 | 28 | 17 | 14 | 18 | 23 |
| 4 | 20 | 17 | 19 | 20 | 23 |
| 5 | 20 | 21 | 20 | 19 | 20 |

We have the isotypic decomposition

$$\mathbb{Q}(S_n) = \bigoplus_{\lambda} V_{\lambda}.$$

In the case n = 5 there are 7 irreducible representations, and we can project the data into these 7 irreducible representations. What we see is the projection on V_3 is pretty large.

| Decomposition of the regular representation | | | | | | | | | | | | | | |
|---|---|-----------|---|-----------|---|-----------|---|----------|---|----------|---|---------|---|-----|
| М | = | V_1 | œ | V_2 | ⊕ | V_3 | ⊕ | V_4 | e | V_5 | Ð | V_6 | œ | V.7 |
| Dim 120 SS/120 | | 1 2286 | | 16 298 | | 25 459 | | 36 78 | | 25 27 | | 16 7 | | 1 |

Consider the representation

$$\rho(\sigma)_{i,j} = \sigma_{\sigma(i),j}.$$

The Fourier transform at this subrepresentation is

$$\hat{f}(\ell) = \sum_{\sigma} f(\sigma) \rho(\sigma)_{i,j}$$

This Fourier transform is exactly the candidate i in position j table. This next table shows the candidate i in position j table with V_1 removed, and we can see it's the same set of numbers normalized so that they add up to zero.

| | Rank | | | | | | | |
|-----------|------|-------|-------|------|-------|--|--|--|
| Candidate | 1 | 2 | 3 | 4 | 5 | | | |
| 1 | - 94 | 371 | 165 | -145 | - 296 | | | |
| 2 | -372 | -70 | 267 | 268 | - 92 | | | |
| 3 | 461 | - 187 | - 354 | - 97 | 178 | | | |
| 4 | 24 | -175 | - 58 | 16 | 193 | | | |
| 5 | - 18 | 62 | - 19 | - 41 | 17 | | | |

Finally we can project the representation on pairs onto V_3 , using the fact that V_3 is the representation on un-ordered pairs minus the occurrences of V_1 and V_2 .

| | Rank | | | | | | | | | | | | |
|-----------|-------|--------|------|-------|------|------|-------|------|------|------|--|--|--|
| Candidate | 1,2 | 1,3 | 1,4 | 1,5 | 2,3 | 2,4 | 2,5 | 3,4 | 3,5 | 4,5 | | | |
| 1.0 | 197 | - 20 | 18 | 140 | 111 | 22 | 4 | 6 | -97 | - 46 | | | |
| 1,2 | -137 | - 20 . | 170 | - 209 | -147 | -169 | -160 | 107 | 128 | 241 | | | |
| 1,3 | 476 | - 00 | -119 | 200 | -9 | 98 | 99 | -65 | 23 | -14 | | | |
| 1,4 | - 189 | 51 | 113 | 24 | 19 | 40 | 56 | - 48 | - 53 | -4 | | | |
| 1,5 | - 150 | 57 | 47 | 45 | 40 | 40 | 00 | -76 | - 39 | 7 | | | |
| 2.3 | - 42 | 84 | 19 | -61 | 30 | -16 | 04 | -10 | 20 | 11 | | | |
| 24 | 157 | -20 | -43 | -25 | -93 | -76 | - 56 | 0 | 00 | 10 | | | |
| 2, 4 | 99 | - 44 | 7 | 15 | -117 | 69 | 25 | 62 | 99 | -13 | | | |
| . 2,5 | 005 | 7 | 72 | 199 | 39 | 140 | 85 | 19 | - 52 | -23 | | | |
| 3,4 | - 260 | -1 | 00 | 70 | 78 | 44 | 47 | -51 | - 36 | -8 | | | |
| 3,5 | - 169 | 10 | 88 | 10 | 5 | -163 | - 128 | 38 | -9 | 26 | | | |
| 4.5 | 296 | -24 | -142 | -130 | -0 | -103 | 120 | 00 | | | | | |

This data can be explained by observing a huge preference for candidates 1, 3 together among one group of voters, witnessed by the number 476, and a not-as-big preference for candidates 4 and 5 witnessed by the 296. It turns out that 1 and 3 are "clinicians" and 4 and 5 are "academicians", two groups within the American Psychological Association which don't get along. Here Fourier analysis provides a clear picture of the data, where classical statistical analysis failed.

3 Unitary Group

Data: zeroes of the Riemann zeta function

$$\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \prod_p \left(1 - \frac{1}{p^s}\right)^{-1}, \text{ for } res > 1$$

It is well known that the zeroes lie within the critical strip $\{0 \le \operatorname{re} s \le 1\}$. If N(T) is defined as the number of zeroes of height T, Riemann showed

$$N(T) = \frac{T}{2\pi} \log \frac{T}{2\pi\ell} + O(\log T).$$

We can rescale the spacings so that they are, on average, spaced 1 apart.

The data in question here is 50000 zeroes from 10^{22} and up.

Hilbert and Polya hypothesized that the zeroes 'look like' the eigenvalues of the unitary matrices.

Pick $M \in U_n$, which has a Haar measure, eigenvalues $\{e^{i\theta_1}, \ldots, e^{i\theta_n}\}$. We can see the distribution of eigenvalues on a circle:

Unitary Eigenvalues

Here's what uniform randomness looks like:

Figure 2: Uniform Points

Here's what they would look like equally spaced:

Figure 3: Picket Fence Model

The eigenvalues are about $\frac{1}{n}$ apart. The zeta zeroes are about $\frac{1}{\log T}$ apart. So we set

$$\frac{1}{n} = \frac{1}{\log T}.$$

For us n = 42 — the zeroes of the zeta functions are supposed to look similar to the eigenvalues of 42×42 unitary matrices. In order to translate the Riemann zeta zeroes from a line into a circle, we take the first 42 zeroes among our 50000 zeta zeroes, and wrap them around the circle, then the next 42, etc. So we have around 1150 circles. (The orientations of each circle were chosen at random.)

The Haar density of of a vector θ of length 42 is given by

$$f(\theta) = \frac{1}{n!2^n} \prod_{j < k} |e^{i\theta_j} - e^{i\theta_k}|^2,$$

a classical formula due to Hurwitz.

So we have X^1, \ldots, X^{1150} circles.

Does this match the Haar measure model from U_n ?

One thing we can try is taking the trace: the sum of 42 random eigenvalues is well approximated by a Gaussian bell shaped curve (by the central limit theorem).

Theorem 3.1 Pick $M \in U_n$ Haar measure.

$$\sup_{A} \left| P(T_n(M) \in A) - \int_a \frac{e^{-|z|^2}}{\pi} dz \right| \le \frac{c}{n!}$$

Here n = 42, so $\frac{c}{n!}$ should be a very tiny number. We can compare the norm-squared "traces" to the expected exponential distribution,

Figure 5: Exponentially Distributed Points

so for this test, the data matches the model.

This is, however, an ad-hoc test. Other tests might reject the model.

For a more systematic test: The characters of U_n are the Schur functions $s_\lambda(x_1, \ldots, x_n)$, where

$$s_0 = 1, s_1 = \sum x_j, s_2 = \sum x_j^2,$$

 $s_{1,1} = \sum_{j \le k} x_j x_k,$

etc. We have orthogonality

$$\mu_N(A) = \frac{1}{N} \#\{i : x^i \in A\}.$$

 $\langle s_{\lambda} \mid s_{\mu} \rangle_{II} = \delta_{\lambda} \mu$

If $\{x^i\}$ is given by Haar measure, define

$$\hat{\mu}_N(\lambda) = \int s_\lambda(m) \mu_N(ds),$$

and $|\hat{\mu}_N(\lambda)|$, as the approximate inner product of s_{λ} and the zeta data, should be small, so

$$T_N = \sum_{\lambda} z^{|\lambda|} |\hat{\mu}_N(\lambda)|$$

gives a statistic.

So V_N converges to Haar $\iff \widehat{V}_N(\lambda) \to 0$.

We can compare these models:

| Data Set | Haar on U_{42} | Zeta Zeros | Picket Fence | 084/2 |
|----------------|------------------|---------------|-----------------|-------------------|
| W _N | 2.17 | 2.31 | 7.94 | 2.04 |
| VV N | 21/17 | 1) with $N =$ | = 1000, n = 42, | $z = \frac{1}{2}$ |

Here we see that the data fits the model quite closely.

The character theory of μ_n comes in when we rewrite T_n :

$$T_N = \int \int \prod_{j,k} \left(1 - z e^{i(\theta_j - i\theta_k)} \right)^{-1} \mu_N(d\theta) \mu_N(d\theta').$$

Similar considerations arise for L-functions and involve other groups: $\mathcal{O}_n, Sp_{2n}, \ldots$

Similar problems arise for data on homogeneous spaces, e.g., in US lotteries, one picks a subset of $\{1, \ldots, n\}$, giving rise to data on $S_n/(S_k \times S_{n-k})$. This is significant for understanding lottery roll-overs — the lottery wants to understand how often these roll-overs happen, which has to do with how people choose their numbers.

4 Monster

All kinds of computational group theory uses random numbers — question, take a group you're interested in, take some random elements, and use the character theory to test whether the data matches the model.

See [3] for a general introduction to this topic. Section 2 is from [4]. The discrete Fourier transform is computed efficiently in [5].

Remark The Fourier transform computed naively takes $O(N^2)$ times, and the fast Fourier transform takes $O(N \log N)$ times, which is a significant improvement.

Section 3 comes from [1]. And to see an example of how one can do this analysis in a Bayesian manner, see [2].
